ABSTRACT
This paper presents a control strategy applied to high power uninterruptible power supplies with a low switching frequency. In the controller design, the gains are determined by minimizing a cost function, which reduces the tracking error and smoothes the control signal. A recursive least square estimator identifies the parameters model at different load conditions. Then the linear quadratic controller gains are adapted periodically. The output voltage is the only state variable measured. The other state variables are obtained by estimation process. Simulation results show that the proposed control strategy offers good performances for either linear and non-linear loads with low total harmonic distortions (THD) even at low frequencies making it very useful for high power applications.

KEY WORDS: Uninterruptible power supplies, Adaptive control, Linear quadratic regulator, Parameter estimation, Simulation.

1 INTRODUCTION
The ultimate goal of uninterruptible power supplies (UPS) system is to supply constant amplitude sinusoidal voltage and constant frequency to load without any interruption in case of a main power failure. The quality of the UPS output voltage is defined by the total harmonic distortion (THD). The most common UPS configuration consists of a battery bank and a static rectifier-inverter-filter that produce a low total harmonic distortion sinusoidal output voltage that supplies the critical load. For such application, system performances are usually measured in terms of transient response and waveform distortions under sudden changes in load parameters [1], [2].

With the cost reduction of microcontrollers and digital signal processors (DSP), the use of digital control technique in power converter has increased. However, high power converters are usually operated at low switching frequencies in order to reduce switching losses. Therefore, advanced control strategies are required to overcome these complications [3], [4], [5].

To design the closed loop control, the model of the system has an important task in the conception of the controller. Some linear models for single phase PWM inverter system have been reported in literature [2], [3]. The output voltage and its derivative, that is proportional to the capacitor current, can be used as the state variables, as well as the output voltage and the inductor current. However, modelling errors and unmodelled dynamics are quite common. They may be a result of simplifications on the model, which can degrade the performance of the system [4].

Many discrete time controllers used to control a single phase inverters in UPS applications were reported in literature, such as predictive control [6],[7], repetitive control [8],[9], optimal state feedback [10] and selective harmonic compensation [11], [12]. Even if most of these schemes offered high performance feedback control results, they still relay on high switching frequencies and involve considerable computational over heads. In this paper a single phase UPS with a low switching frequency is proposed in order to minimise switching losses and improve system efficiency. An adaptive linear quadratic regulator for single-phase UPS application is proposed. The regulator is a useful tool in modern optimal control design. For the proposed controller, a recursive least square estimator identifies the plant parameters which are used to compute the regulator gains periodically. The quadratic cost function parameter is chosen in order to reduce the energy of the control signal. Only the output voltage can be measured and the inductor current is not measurable. As a result, an observer is used to estimate the inductor current. Using a suitable filter the effect of disturbances on the response of the system will be decreased. The simulations were carried out using MATLAB Simulink.

This paper is organized as follows: After the introduction, the global model of the plant is described in section (2), Theoretical analysis of the controller, RLS estimator and Kalman filter descriptions are reported in sections (3), (4) and (5) respectively. Simulation results and discussion are
presented in section (6) followed by the conclusion in the final section.

2 DESCRIPTION OF THE PLANT

The single-phase PWM inverter is shown in Fig.1, the LC filter and the resistive load R are considered to be the plant of the system.

The inverter is controlled by the unipolar PWM. The power switches are turned on and off at the carrier frequency.

The plant can be modelled by the state space variable \( v_c \) and \( i_L \):

\[
\begin{bmatrix}
  v_c \\
  i_L
\end{bmatrix} =
\begin{bmatrix}
  -\frac{1}{RC} & \frac{1}{C} \\
  -\frac{1}{L} & 0
\end{bmatrix}
\begin{bmatrix}
  v_c \\
  i_L
\end{bmatrix} +
\begin{bmatrix}
  0 \\
  \frac{1}{L}
\end{bmatrix}
\begin{bmatrix}
  u \\
  y
\end{bmatrix},
\]

or

\[
\dot{x} = Ax + Bu, y = Cx,
\]

Then, a discrete time model of the plant obtained by the forward method and sample time \( T_s \) is given by:

\[
x(k+1) = A_d x(k) + B_d u(k), y(k) = C_d x(k),
\]

Where

\[
x(k) = \begin{bmatrix} v_c(k) & i_L(k) \end{bmatrix}^T.
\]

\[
A_d = I + T_s A, \quad B_d = T_s B,
\]

3 LINEAR QUADRATIC REGULATOR

The adaptive linear quadratic regulator controller has the objective of tracking the discrete sinusoidal \( r(k) \) reference in each sample instant.

The system output \( y(k) \) is the capacitor voltage in the discrete form \( v_c(k) \). The state variables used in the (LQR) are the measured output voltage \( v_c(k) \), the estimated inductor current \( i_L(k) \), the integrated tracking error \( v(k) \); all with a feedback action and the discrete reference \( r(k) \) and its derivative \( \dot{r}(k) \) with a feed forward action. Each state variable has weighting \( K_i \) tuned according to \( \theta(k) \), which contains the plant parameters identified by the RLS estimator. The control system shown in Fig.2 is therefore proposed.
Then, in the proposed system, the state vector \( z(k) \) is defined as:
\[
z(k) = \begin{bmatrix} v_x(k) & \hat{i}_c(k) & v(k) & r(k) & \dot{r}(k) \end{bmatrix}^T,
\]
(5)
and the LQR control signal is given by
\[
u_{LQR}(k) = -Kz(k),
\]
(6)
To design the optimal gains \( K_1, K_2, \ldots, K_5 \), the system must be represented in the form:
\[
z(k + 1) = Gz(k) + Hu_{LQR}(k),
\]
(7)
Where each state variable is calculated by a difference equation. The two first variables of vector \( z(k) \) are obtained by (3). The signal \( v(k) \) is:
\[
v(k + 1) = e(k + 1) + v(k),
\]
(8)
Where the error is given by:
\[
e(k) = r(k) - y(k),
\]
(9)
From (3), (8) and (9) results the difference equation for
\[
v(k + 1) = v(k) + r(k) + T_s \dot{r}(k) - C_d A_d x(k) - C_d B_d u_{LQR}(k)
\]
(10)
The continuous time reference variables are:
\[
\begin{bmatrix} r(t) \\ \dot{r}(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -\omega^2 & 0 \end{bmatrix} \begin{bmatrix} r(t) \\ \dot{r}(t) \end{bmatrix}, \dot{r} = Rr,
\]
(11)
This system generates a sinusoidal reference when initiated with initial values:
\[
r(0) = 0, \dot{r}(0) = wV_p .
\]
where \( V_p \) is the sine wave amplitude and \( w \) is the angular frequency.
In the discrete form, using a sample period \( T_s \), the subsystem (11) is given by:
\[
n(k + 1) = R_d n(k),
\]
(12)
Where
\[
n(k) = [r(k) \ \ \dot{r}(k)],
\]
(13)
\[
R_d = I + T_s R,
\]
(14)
Then, using the state equations (3), (10) and (12), the closed loop system representation becomes:
\[
\begin{bmatrix} x(k + 1) \\ v(k + 1) \\ n(k + 1) \end{bmatrix} = \begin{bmatrix} A_d & 0 & 0 \\ -C_d A_d & 1 & C_d R_d \\ 0 & 0 & R_d \end{bmatrix} \begin{bmatrix} x(k) \\ v(k) \\ n(k) \end{bmatrix} + \begin{bmatrix} B_d \\ -C_d B_d \end{bmatrix} u_{LQR}(k)
\]
\[
y(k) = [C_d & 0 & 0] \begin{bmatrix} x(k) \\ v(k) \\ n(k) \end{bmatrix}^T,
\]
(15)
The optimal gains of the control law (6) are those that minimize the following cost function:
\[
J = \frac{1}{2} \sum_{k=0}^{\infty} \{e^T(k)Qe(k) + u^T(k)R_u u(k)\},
\]
(16)
Where \( Q \) and \( R_u \) are chosen as positive definite matrices that set the weighting of states and the control signal respectively.

The \( K \) gains can be obtained through the evaluating the Riccati equations \[13\]. as follows:
\[
S(k) = G^T S(k + 1) G + Q - \left[H^T S(k + 1) G \right]^T \times \left[R_u + H^T S(k + 1) H \right]^{-1} \left[H^T S(k + 1) G \right],
\]
(17)
\[
K(k) = R_u^{-1} H^T \left(G^T \right)^{-1} (S(k) - Q),
\]
(18)
A good flexibility in the design of the controller is provided by the selection of \( Q \) and \( R_u \) matrixes.

### 4 RECURSIVE LEAST SQUARES (RLS) ESTIMATOR

To estimate the plant parameters when the load conditions are variable, a RLS algorithm is used \[14\]. The discrete plant model with a zero order hold is given by:
\[
\frac{y(z)}{u(z)} = \frac{\theta_1}{z^2 + \theta_1 z + \theta_2},
\]
(19)
The difference equation of the estimated output is:
\[
y(k) = -\theta_1 y(k - 1) - \theta_2 y(k - 2) + \theta_1 u(k - 2),
\]
(20)
or
\[
\hat{y}(k) = \theta^T(k) \Psi(k - 1),
\]
(21)
Where
\[
\theta(k) = \begin{bmatrix} \theta_1 & \theta_2 & \theta_3 \end{bmatrix},
\]
(22)
and
\[
\Psi(k) = \begin{bmatrix} -y(k - 1) & -y(k - 2) & u(k - 2) \end{bmatrix},
\]
(23)
The RLS gains are calculated using:

\[ L(k) = \frac{p(k-1)\Psi(k)}{1 + \Psi^T(k)p(k-1)\Psi(k)}, \]  

(24)

The RLS covariance matrix is given by:

\[ p(k) = p(k-1) - \frac{p(k-1)\Psi(k)\Psi^T(k)p(k-1)}{1 + \Psi^T(k)p(k-1)\Psi(k)}, \]  

(25)

and the plant parameters \( \theta \) are recursively obtained by:

\[ \hat{\theta}(k) = \hat{\theta}(k-1) + L(k)\left[ y(k) - \Psi^T \hat{\theta}(k-1) \right], \]  

(26)

Where:

\[
\hat{A}_d = \begin{bmatrix} 0 & -\hat{\theta}_2 \\ 1 & -\hat{\theta}_1 \end{bmatrix}, \quad \hat{B}_d = \begin{bmatrix} \hat{\theta}_3 \\ 0 \end{bmatrix}, \quad \hat{C}_d = \begin{bmatrix} 0 & 1 \end{bmatrix}, \]

(27)

Then, it is possible to identify the plant parameters to a range of different loads through the substitution of matrixes (27) into system (15) and proceed there often with the LQR gains design in real time.

5  KALMAN FILTER

Since only the output voltage is measured, a Kalman filter [13], [15] is used to estimate the inductor current state.

\[
x(k+1) = A_d x(k) + B_d u(k) + w(k) \\
y(k) = C_d x(k) + v(k),
\]

(28)

The random variables \( w(k) \) and \( v(k) \) represent the process and measurement noise respectively. They are assumed to be independent of each other and with normal probability distributions such that:

\[
E[w(k)^T w(k)] = R_w > 0 \\
E[v(k)^T v(k)] = R_v > 0, \\
E[w(k)^T v(k)] = 0
\]

(29)

In practice, the process noise covariance and measurement noise covariance matrices might change with each time step or measurement. However, here, it is assumed that they are presented below [15].

The Kalman gains are given by:

\[ K_g(k) = \left( M(k)C_d^T \right) \left( C_d M(k)C_d^T + R_v \right)^{-1}, \]

(30)

and the estimated variable, the inductor current, is

\[ i_L = \hat{x}_L(k) = \begin{bmatrix} 0 & 1 \end{bmatrix} \hat{x}(k), \]

(31)

The following recursive equations are used:

\[ P_k(k) = M(k) - K_g(k)C_d M(k), \]

(32)

and

\[ M(k) = \left( A_d P_k(k) A_d^T \right) + \left( B_d R_u B_d^T \right), \]

(33)

After each time and measurement update pair, the process is repeated with the previous posterior estimates used to project or predict the new a priori estimates.

6  SIMULATION RESULTS

The simulation work is carried out according to the proposed block diagram presented in Fig.3. The inverter system controlled by linear quadratic regulator algorithm is realized in order to study the output voltage \((V_c)\) performance under linear and nonlinear loads. The plant controller parameters, algorithm constants and other system specifications are presented in table1.

For a linear load, the input and output voltage waveforms, estimated and measured inductor currents as well as estimated parameters are shown in Fig.4, 5 and 6 respectively.

A linear load output voltage and current with values of R and K (gains) taken from table1 are illustrated in Fig.7 and the output voltage frequency spectrum is presented in Fig.8. From this spectrum, the THD is calculated and the obtained value is 1.12% showing a high quality output voltage.

For a nonlinear load, the output voltage, the output current and the output voltage frequency spectrum are shown in Fig.9 and 10 respectively. The THD obtained from the voltage spectrum is equal to 1.61% proving a high quality output voltage. Fig.11 depicts the transient response of the output voltage compared to the reference. One notices that the dynamic time vanishes in brief time. Fig.12 shows the output voltage tracking the reference voltage efficiently in the case of linear load disturbance. From this figure, it is clear that the proposed LQR regulator is efficient.

A Linear Quadratic Regulator was successfully developed for a single phase UPS application. The linear quadratic regulator gains are calculated by minimizing a cost function which can be changed by the designer by modification of the weighting factors. Therefore, it is possible to reduce the control efforts in tracking the sinusoidal reference. The RLS estimator identifies the plant parameters which are used to compute LQR gains periodically.

The discrete control law has shown good performances to linear and nonlinear loads when operated at low switching frequency. Theses characteristics make this scheme suitable to be used in high power applications as well as to be implemented through a low cost micro controller.
